

## 8 Borel subspaces

The central notion in measure theory is that of a measurable subset — it is the defining concept of a measurable space. With quasi-Borel spaces, measurable subsets are a derived notion, but take a nonetheless central role.

**▮8.1.** A *measurable*, or *Borel*, subset in a qbs  $A$  is a subset  $U \subseteq \downarrow A$  such that the preimage under every random element  $\alpha \in \mathcal{R}_A$  is a Borel subset of the reals:  $\alpha^{-1}[U] \in \mathcal{B}$ . We denote by  $\mathcal{B}_A$  the set of Borel subsets of  $A$ .

- Show that the measurable sets  $\mathcal{B}_A$  in a qbs  $A$  form a  $\sigma$ -algebra, and every random element is measurable w.r.t. this  $\sigma$ -algebra.

We denote the resulting measurable space by  $\uparrow^{\text{Meas}} A := \langle \downarrow A, \mathcal{B}_A \rangle$ , and call it the *free measurable space* over  $A$ .

- Show that  $U \subseteq \downarrow A$  is measurable iff its indicator function  $[- \in U] : A \rightarrow \uparrow^{\text{Qbs}} 2$  is a qbs morphism from  $A$  into the discrete qbs on the two-element set.  $\triangleleft$

**▮8.2.** Find the Borel sets of the discrete qbs  $\uparrow^{\text{Qbs}} 2$  and the indiscrete qbs  $\downarrow_{\text{Qbs}} 2$  on two elements. Generalise this result to the discrete and indiscrete qbses over any set  $X$ .  $\triangleleft$

**▮8.3.** Show that the Borel subsets of  $\mathbb{R}$  in the standard sense coincide with the measurable subsets of the qbs  $\mathbb{R}$ .  $\triangleleft$

**▮8.4.** Let  $A$  be a qbs and  $X \subseteq \downarrow A$  be a subset.

- Show that if  $U \subseteq \downarrow A$  is Borel in  $A$ , then  $U \cap X$  is Borel in the subspace  $X$ :

$$U \in \mathcal{B}_A \implies U \cap X \in \mathcal{B}_X$$

- Show that if  $X$  is itself a Borel subset, then  $\mathcal{B}_X \subseteq \mathcal{B}_A$ .
- Show that the previous clause may fail if  $X$  is not Borel.  $\triangleleft$

The Borel subsets of a subspace can be quite different from the Borel subsets of its superspace. For example, we may have a Borel subset  $V \in \mathcal{B}_X$  of the subspace that is not of the form  $U \cap X$  for any Borel subset  $U \in \mathcal{B}_A$  of the superspace.

Here's the intuition:

- A subset  $U$  in a qbs is measurable unless there is some random element that stops it from being measurable by mapping  $U$  onto a non-Borel inverse image.
- ‘Wild’ random elements may not factor through a subspace embedding  $X \hookrightarrow A$ .
- So a subspace may have more Borel subsets in  $X$  than in its superspace.

If you want to see this intuition playing out, here is how to construct a counter-example:

**▮8.5.** Let  $C_1 \subseteq \mathbb{R}$  be a non-Borel subset and  $C_2 := \mathbb{R} \setminus C_1$  its complement, also non-Borel. Let  $\mathbb{3} := \{0, 1, 2\}$  be a three-element set, and define two primitive random elements  $\alpha_i : \mathbb{R} \rightarrow \mathbb{3}$ :

$$\alpha_0 r := \begin{cases} r \in C_1 : 0 \\ r \in C_2 : 2 \end{cases} \quad \alpha_1 r := \begin{cases} r \in C_1 : 1 \\ r \in C_2 : 2 \end{cases}$$

Take  $A := \langle \mathbb{3}, \text{Cl}_{\text{qbs}} \{\alpha_0, \alpha_1\} \rangle$  to be the qbs over  $\mathbb{3}$  with the smallest metaphorology (see Ex.7.9) containing  $\alpha_0$  and  $\alpha_1$ , and take  $X := 2 \subseteq \mathbb{3}$ .

- Show that  $X, \{0\}, \{0, 2\} \notin \mathcal{B}_A$  are not Borel subsets in  $A$ .
- Show that if  $\alpha \in \mathcal{R}_A$  is a random element in  $A$ , then either  $\alpha$  is  $\sigma$ -simple or  $2 \in \text{Im}(\alpha)$ .
- Show that  $\{0\} \in \mathcal{B}_X$  is a Borel subset of the subspace  $X$ .  $\triangleleft$

✓8.6. Let  $f : A \rightarrow B$  be a qbs morphism. Show that:

- The inverse image under  $f$  restricts to a function  $\mathcal{B}_f : \mathcal{B}_B \rightarrow \mathcal{B}_A$ .
- The underlying function  $\ulcorner f \urcorner : \ulcorner A \urcorner \rightarrow \ulcorner B \urcorner$  is a measurable function  $\ulcorner f \urcorner^{\text{Meas}} : \ulcorner A \urcorner^{\text{Meas}} \rightarrow \ulcorner B \urcorner^{\text{Meas}}$ .  $\triangleleft$

The collection of Borel sets has a universal property: it allows us to connect measurable spaces with quasi-Borel spaces as follows:

✓8.7. For a measurable space  $M$ , define its set of *random elements* by  $\mathcal{R}_M := \text{Meas}(\mathbb{R}, M)$ .

- Show that  $\mathcal{R}_M$  is a metaphorology, that is,  $\ulcorner M \urcorner_{\text{Qbs}} := \left( \ulcorner M \urcorner_{\text{Set}}, \mathcal{R}_M \right)$  is a qbs.
- For every measurable function  $f : M \rightarrow N$  between measurable spaces, show that its underlying function is a qbs morphism  $\ulcorner f \urcorner_{\text{Qbs}} : \ulcorner M \urcorner_{\text{Qbs}} \rightarrow \ulcorner N \urcorner_{\text{Qbs}}$ .
- Noticing that  $\ulcorner - \urcorner_{\text{Qbs}} : \text{Meas} \rightarrow \text{Qbs}$  is a (faithful) functor, show that it has a left adjoint equipping a qbs with its set of Borel subsets:  $\ulcorner - \urcorner^{\text{Meas}} \dashv \ulcorner - \urcorner_{\text{Qbs}}$ .  $\triangleleft$

✓8.8. The free qbs functor  $\ulcorner - \urcorner^{\text{Qbs}} : \text{Set} \rightarrow \text{Qbs}$  doesn't preserve countable products.  $\triangleleft$

This point is a natural place to stop, but if you're having fun with this material, then the rest of this sheet studies the relationships between natural notions of 'subspace'.

- $m : A \rightarrowtail B$  Monomorphisms: injective qbs morphisms.
- $m : A \hookrightarrow B$  Subspace embedding: injective on elements and surjective on random-elements that factor through the image.
- $m : A \rightarrowtail B$  Borel injections: monomorphisms whose image is a Borel subset.
- $m : A \hookrightarrow B$  Borel embeddings: subspace embeddings whose image is a Borel subset.

We establish their following mutual relationships, where all inclusions are proper:

✓8.9. Place the following injections in the hierarchy of monomorphisms above:

- The injection  $\top := \lambda x.1 : \ulcorner 1 \urcorner^{\text{Qbs}} \rightarrowtail \ulcorner 2 \urcorner^{\text{Qbs}}$ .
- The injection  $\lambda x.x : \ulcorner 2 \urcorner^{\text{Qbs}} \rightarrowtail \ulcorner 2 \urcorner^{\text{Qbs}}$ .

- The injection  $\lambda x.x : \mathbb{R}^{\mathbf{Qbs}}_2 \rightarrow \mathbb{R}^{\mathbf{Qbs}}_3$ .
- The (subspace) inclusion  $\lambda x.x : C \hookrightarrow \mathbb{R}$  where  $C$  is a non-Borel subset of  $\mathbb{R}$ .  $\triangleleft$

▮8.10. Let  $m : S \rightarrow A$  be a qbs morphism. Show that the following are equivalent:

- $m$  is a subspace embedding, i.e.: there is a subset  $X \subseteq A$  and an isomorphism  $m' : B \xrightarrow{\cong} X$  satisfying:

$$\begin{array}{ccc} S & \xrightarrow{m} & A \\ m' \downarrow \cong & = & \downarrow \\ X & \xrightarrow{\lambda x.x} & A \end{array}$$

- $m$  is *right-orthogonal* to every epimorphism  $e : B \twoheadrightarrow C$ : for every commuting square as on the left, there is a unique morphism  $h : C \rightarrow S$  commuting the triangles on the right:

$$\begin{array}{ccc} B & \xrightarrow{e} & C \\ f \downarrow & = & \downarrow g \\ S & \xrightarrow{m} & A \end{array} \quad \Longrightarrow \quad \begin{array}{ccc} B & \xrightarrow{e} & C \\ f \downarrow & \xrightarrow{h} & \downarrow g \\ S & \xrightarrow{m} & A \end{array}$$

(Morphisms that have this property are called *strong monomorphisms*.)

- $m$  is an *equaliser* of some parallel pair of morphisms  $f, g : A \rightarrow B$ :
  - $m$  *equalises*  $f$  and  $g$ :

$$\begin{array}{ccccc} & & A & & \\ & m \nearrow & & f \searrow & \\ S & & & & B \\ & m \searrow & & g \nearrow & \\ & & A & & \end{array}$$

- and every equalising morphism  $e : C \rightarrow A$  factors uniquely through  $m$ :

$$\begin{array}{ccc} E & \xrightarrow{e} & A \\ & \searrow & \downarrow f \\ & & B \\ & \nearrow & \downarrow g \\ E & \xrightarrow{e} & A \end{array} \quad \Longrightarrow \quad \begin{array}{ccc} E & \xrightarrow{e} & A \\ & \searrow h & \downarrow m \\ & & E \end{array}$$

(Morphisms that have this property are called *regular monomorphisms*.)  $\triangleleft$

▮8.11. A class of qbs-morphisms is *admissible* when, for every pullback square as follows, in which  $m \in \mathcal{M}$  then necessarily  $\pi_1 \in \mathcal{M}$ :

$$\begin{array}{ccc} f \bowtie m & \xrightarrow{\pi_2} & X \\ \pi_1 \downarrow & \lrcorner & \downarrow m \\ A & \xrightarrow{f} & B \end{array}$$

Show that:

- Monomorphisms are admissible.
- Subspace embeddings are admissible.
- Borel embeddings are admissible.  $\triangleleft$

▮8.12. Let  $\mathcal{M}$  be an admissible class. An  $\mathcal{M}$ -*classifier* is a pair  $\langle \Omega_{\mathcal{M}}, \tau_{\mathcal{M}} \rangle$  consisting of:

- a space  $\Omega_{\mathcal{M}}$ ; and
- an  $\mathcal{M}$ -morphism  $\tau_{\mathcal{M}} : \mathbb{1} \rightarrow \Omega_{\mathcal{M}}$

such that for every  $\mathcal{M}$ -morphism  $m : X \rightarrow A$ , there is a unique qbs morphism  $\varphi : A \rightarrow \Omega_{\mathcal{M}}$  for which the following square is a pullback square:

$$\begin{array}{ccc} X & \xrightarrow{\langle \rangle} & \mathbb{1} \\ m \downarrow & \lrcorner & \downarrow \tau_{\mathcal{M}} \\ A & \xrightarrow{\varphi} & \Omega_{\mathcal{M}} \end{array}$$

In this case, we denote this unique  $\varphi$  by  $[- \in m[X]]_{\mathcal{M}} : A \rightarrow \Omega_{\mathcal{M}}$ .

Show:

- If  $\mathcal{M}$  has a classifier in **Qbs**, then  $\mathcal{M}$  contains only subspace embeddings.
- The indiscrete Booleans  $\langle \downarrow_{\mathbf{Qbs}}, \mathbf{true} \rangle$  form a subspace embedding classifier.
- The discrete Booleans  $\langle \uparrow_{\mathbf{Qbs}}, \mathbf{true} \rangle$  form a Borel embedding classifier.
- There are no monomorphism nor Borel monomorphism classifiers in **Qbs**. ▮

A *factorisation system*  $\langle \mathcal{E}, \mathcal{M} \rangle$  is a pair of classes of morphisms such that:

- $\mathcal{E}$  and  $\mathcal{M}$  are closed under composition and contain all isomorphisms;
- every morphism  $f : A \rightarrow B$  has an  $\mathcal{E}$ - $\mathcal{M}$  *factorisation*:

$$\begin{array}{ccc} A & \xrightarrow{f} & B \\ & \searrow \quad \nearrow & \\ & X & \end{array} \quad \begin{array}{c} \\ = \\ \mathcal{E} \ni e \quad m \in \mathcal{M} \end{array}$$

- every morphism  $m \in \mathcal{M}$  is right-orthogonal to every morphism  $e \in \mathcal{E}$  (cf. Ex.8.10):

$$\begin{array}{ccc} B & \xrightarrow{e \in \mathcal{E}} & C \\ f \downarrow & = & \downarrow g \\ S & \xrightarrow{m \in \mathcal{M}} & A \end{array} \quad \Longrightarrow \quad \begin{array}{ccc} B & \xrightarrow{e \in \mathcal{E}} & C \\ f \downarrow & \xrightarrow{h} & \downarrow g \\ S & \xrightarrow{m \in \mathcal{M}} & A \end{array}$$

▮8.13. Show that  $\langle \mathbf{epi}, \mathbf{subspace\ embedding} \rangle$  is a factorisation system. ▮

▮8.14. A qbs morphism  $e : A \rightarrow B$  is a *strong epimorphism* when its action on random elements is surjective:

$$e \circ - : \mathcal{R}_A \twoheadrightarrow \mathcal{R}_B$$

Show that:

- The projection  $\pi_1 : \mathbb{R}^2 \rightarrow \mathbb{R}$  is a strong epimorphism.
- Every strong epimorphism is surjective.
- Every map from a non-empty space into the terminal space  $\langle \rangle : X \rightarrow \mathbb{1}$  is a strong epimorphism.

- If  $f_i : A_i \rightarrow B_i$ ,  $i \in I$ , is a countable collection of strong epimorphisms, then their product  $\prod_{i \in I} f_i : \prod_{i \in I} A_i \rightarrow \prod_{i \in I} B_i$  is a strong epimorphism.  $\triangleleft$

✓8.15. Find an epimorphism that is not a strong epimorphism.  $\triangleleft$

✓8.16. Show that  $\langle \text{strong epimorphisms}, \text{mono} \rangle$  is a factorisation system.  $\triangleleft$
